# Lab 7 Preparation

# Lab 7 Components

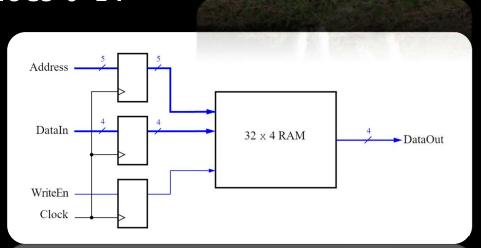

Part I: Create a memory unit

Part II: Interface with the RGB Video

Part III: RGB Video animation (bonus)

# Part I: Memory Unit

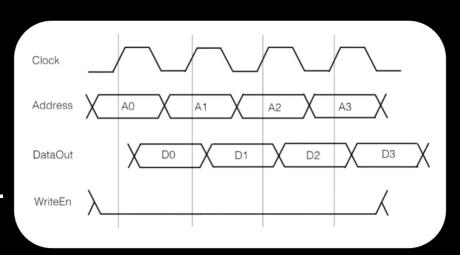

- Creating a mini-RAM unit.
- Make use of the built-in RAM
  - Follow lab instructions to create
    a 4-bit RAM unit with 32 words.
  - Fill the RAM with values 0-F.
- Once completed, connect this RAM to the HEX display.

# Part I: Read & Write Timing

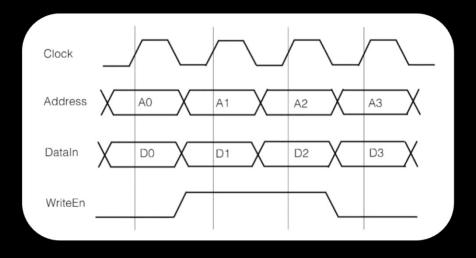

#### Read:

 Note slight delay after clock signal, before data appears.

#### Write:

 Note that only D1 and D2 are written (because of the WriteEn signal).

# Part I: Filling memory

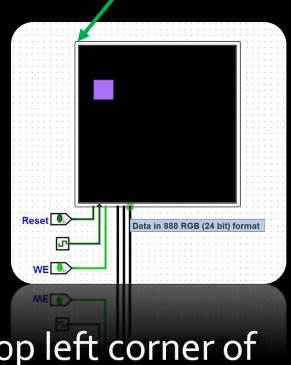

Connect address register --- and data register to RAM.

Fill all RAM locations with increasing values, starting at 0 at address 00000.

Connect output to 7-segment display.

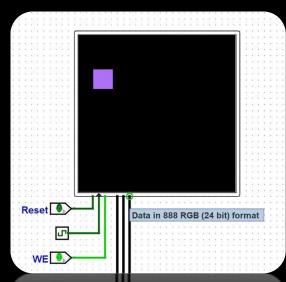

- The RGB Video component models the VGA display in the lab workstations.
- For this part, given input coordinates X and Y, draw a 16x16 box of coloured pixels, using X and Y as the top left corner of the box.

Location

(0,0)

- The RGB Video component has 6 inputs:
  - Reset
  - Clock
  - Write Enable
    - Like lifting/dropping pen on paper.
  - X Coordinate
  - Y Coordinate
  - Data in 888 RGB (24 bit) format
    - Three sections of 8 bits, representing the RGB values for the pixel (see next slide for more detail)

- Light colours are additive.
  - As opposed to paint, which is subtractive.
  - Light is made of red, green and blue components.
    - White light is the combination of all three.
- To create a colour, set the 8-bit values for the red, green and blue components and concatenate them into a 24-bit value.
  - Black =  $0 \times 000000$ , White =  $0 \times FFFFFF$

- Circuit components needed:
  - RGB Video
    - built into Logisim, check the handout for input details
  - Datapath
    - Takes in:
      - X and Y (through switches)
      - control signals (reset, clock, enable etc.)
  - FSM:
    - Controls datapath to load X and Y values, and iterate through the pixel locations that need to be updated (relative to X and Y).

#### Hints:

- Have tests to verify that each component works on its own.
  - Try using the RGB Video to draw a single pixel,
  - Make sure the datapath works on its own,
  - Verify the state transitions of the FSM.
- Consider using counters to store the offsets from X and Y that need to be displayed.
- It's Lab 7. You have full freedom to implement this however you like ©

# Part III: Animation (bonus)

- Note: This part is optional, but can be done for bonus marks in the course.
- Animate a box by drawing it, then waiting, then drawing another at a different location, then waiting...
- Many projects will use animation in some form, so you should try this part out!
  - Also...bonus marks! ©
